Chapter 5

Inventory Management Overview

Introduction

A system to keep proper control of Inventory is a prerequisite for buying decisions, answering customer questions and deciding the production program. Different organisations require different levels of detail and support for Inventory Management decisions, and indeed this might vary within the same organisation. However, the basics of defining items, recording movement, even calculating balances and providing valuations will be common to all such companies.

The Inventory Management application provides a wide spectrum of facilities for the recording, valuation and management of Inventory. These facilities are the bed-rock on which the interface to the product are built. The application may be installed in a simple organisation which views its Inventory as a single logical unit, or with equal ease in a multi-warehousing organisation with separate raw material, finished goods and component stores. Multiple stockrooms or stores may be created, with the ability to maintain different stock investment policies in each. This is achieved without data redundancy as the same definition is used throughout.

Relationships To Other Applications

Inventory Management is a fully standardised application and as such operates under the control of the system manager.

There are no pre-requisite applications for this module (apart from the system manager), moreover this application is a pre-requisite for all the interfaced applications.

Although the application is designed to operate as a fully integrated application, it can be operated in a very simple fashion as a stand-alone system, including facilities to record sales and purchase activity as well as providing Inventory recording and control.

Application Configuration

As with all applications Inventory Management can be operated for a number of companies, the characteristics of each being maintained on a control file. The application is controlled by setting up data for the company and then for each stockroom within the company. You can add Stockrooms after the initial implementation of the application.

You can set certain policies as a default at the company level. These are:

- Costing Method.
- General Ledger codes.
- Period for usage calculation (week or month).
- Stock Management Policy factors:
 - Method of calculation.
 - Re-order quantity factor.
 - Stock carrying rate.
 - Supply order placement cost.

These policies and parameters are used throughout the operation of the application unless overridden at the level of the item or at the time of the transaction.

It is necessary to define each stockroom where stock will be held. You can set three important policies at this level:

1. You can exclude the stockroom from valuation, that is, for consignment stocks.
2. You can exclude certain transactions from use in the stockroom.
3. You can create a value usage matrix to manage the stock investment policy of the stockroom. Nine value/usage bands may be created and target minimum and maximum weeks of stock defined.

In order to calculate average usage, you must define two factors;

1. The time interval in weeks or months
2. The periods to be taken into account in the calculation of average usage. The time interval is set on the company record and a number of profiles may be maintained detailing which of the previous sixty time periods (weeks or months) will be included in the calculation.

Inventory Management Set Up Data

The maintenance functions of the Inventory Management application enable the creation and amendment of master files and data files which are fundamental to its operation. The application will then build the necessary transaction and movement histories as work progresses.

There are a number of common features in the way in which data is maintained, these are:

- The standard (product) and description search routines.
- A standard method of selecting codes from a displayed list.

The following data can be maintained:

- Standard Codes and Descriptions.
- (product) Master Details.
- Alternative Products.
- Stockroom or Balance Details.
- Calendar.

Standard Codes And Descriptions

A Descriptions or Parameters File is used in most applications for a number of purposes. Primarily, it enables codes to be set up with standard descriptions. This provides for validation at the time of data entry and also the display of descriptions on both screens and reports. In some specific instances a rate is also stored, for example, in the case of the VAT Table. The application has a small number of standard parameters that must be present for its successful operation. The Inventory Management Application Descriptions file is the one used by standard applications. The standard parameters held on this file, therefore, include those required by all Logistics and Customer Services applications.

Item Data

Inventory Management is designed to have a flexible data structure, but without incurring data redundancy. In order to achieve this there is an Item Master record which identifies the item to the application and indeed to all applications. This holds the static descriptive and classification data. If more data is required in Inventory or any other application then a record of that information is set up and maintained in the originating application.

The following are examples of the additional data:

Inventory Management

- Stockroom balance records.
- Lot or batch records.
- Extended internal and external text.
- Alternatives.
- Search family codes.

- Sales Order Processing.
- Pricing Details.
- Default Size Distribution.

Purchase Order Management

- Item/supplier profiles.

Production Applications

- Production profile.

Forecasting

- Item/Forecast profile.

DRP

- Item/DRP profile.

In this way it can be seen that the application requires the entry and maintenance of only that data necessary to run the operational applications in any company's system.

The Item Master details can be grouped into the Static Part record which includes:

- Description.
- Six different Analysis Codes.
- Units of Measure (UOM) - you can define three for each (item).
- VAT Codes.
- Costing method, costs and default General Ledger Codes.
- Sourcing Warehouse (Primary Warehouse).
- Supersession details.
- Search Families.

Stockroom Balance/Warehouse Select

You can define on or more stockrooms for any item. A stockroom is a discrete area within a company where stock is recorded and controlled separately from other company stocks. Depending upon the type of company a stockroom may be used to define divisions, depots, warehouses, stores, an area within a store or even van stock. If such distinctions are not required a single stockroom is created to record the total company stock of the item.

The Static Warehouse information is concerned with:

- Units of measure at the Stockroom.
- Inventory Management Policy and Control.
- Balance Data.
- Costs.
- Preferred Suppliers.

The warehouse select allows the user to select more than one warehouse where the product may be stored, and so on.

Batch Control/Lot Traceability

The ability to track items at Batch or Lot Number is available.

If warehouse control is required, then the Warehousing application should be installed.

Alternative Items

For any item one or more alternatives may be nominated. When you create the relationship you can state whether or not the relationship is reversed. This facility is used by the Sales Order Processing functions to offer customers alternatives if an item is not currently available.

Kit Lists

A kit of items may be set up for use within Sales Order Processing. This is a single level kit with a single parent and any number of components.

Where kits are sold, you need to consider the impact of updates to Sales Analysis.

Note: You can pass details of the whole kit, parent only or components.

Calendar Control

The Inventory Management application must concern itself with dates, week endings and period endings, in order to perform reconciliation, usage calculations and the analysis of information. Both week end dates and period end dates can be maintained for all operational years. These should be set up before processing begins.

Processing

There are four main processing activities involved in the operation of the Inventory Management application. These are as follows:

- Movement Transactions.
- Stock Counting.
- Stock Management.
- Periodic Processing.

The first two functions are concerned with the performance of the stock recording aspects of Inventory, the third is concerned with deciding what stock should be where, and the fourth with building the database to aid management decisions. As the movement transactions are applied to the balances interactively, the displayed balance reflects the latest information in the system. Therefore, supply and despatch decisions can be made in greater confidence. The Inventory application can be installed in isolation. However, if Purchasing, Manufacturing and Sales Systems are installed most of the movements will be performed in these operational systems. The Inventory application will concern itself exclusively with counting, housekeeping and stock management decisions.

Movement Transactions

The primary purpose of an Inventory movement is to record an action within the application and to calculate its effect on the stock balance. In its simplest form a miscellaneous receipt booking straight into Inventory increases the physical stock. However, a Customer Order Issue, will reduce the physical stock and the balance of the stock allocated to orders.

The following movement types are available:

- Customer Order Issue.
- Miscellaneous Issue.
- Purchase Order Receipt.
- Miscellaneous Receipt.
- Adjustment to Physical Stock.
- Adjustment to Allocated Stock.
- Adjustment to Frozen Stock.
- Record Purchase Order.
- Transfer In and Out (Move from one stockroom to another on a single transaction).
- Carton Stock Adjustment.

Each movement updates the appropriate balance field on the item stockroom balance. If the item is defined as being Batch/Lot or Serial controlled you must enter the additional control number. A subset of the balances are maintained for the lower level record.

You can enter costs for the movement and depending upon the movement type and the costing method the database will be updated appropriately.

There are four ways of valuing stock movements. These are:

- Average Cost - The average cost of stock in the stockroom is recalculated every time a receipt is made. This average cost is used to value issues. (Receipts are valued at receipt cost.)
- Standard Cost - The standard cost for the part is either rolled over from the manufacturing application or directly maintained. This cost is used to value all movements, both receipts and issues.
- FIFO Cost - This is the acronym for First In First Out. Each receipt for the Product is maintained as a separate balance and as an issue is made the product is consumed. The first receipt to arrive is the first receipt balance to be used for issues. The cost of the issue is taken from the receipt balance. The FIFO sequence is maintained by time as well as date. If the part is lot controlled then the FIFO operates within lot.
- Latest Cost - This is when the latest cost of the receipt issued to value the stock.

You set the default or preferred costing method on the company profile. However, you can set a different costing method for a particular item, when it is defined. All costs are kept in up to five decimal places of base currency. The latest cost of all the product is recorded and the average cost calculated whatever the costing method. If, for example, the valuation method is FIFO this can be simply compared with the average and latest cost on an enquiry screen.

For each inventory movement a record is written to a transaction file. This provides a full audit trail of movements. The information held includes:

- Movement type.
- Supplier or Customer.
- Quantity moved.
- Value of the movement.
- Resulting stockroom balance.
- Batch/Lot number.
- Date and Time of movement.
- Person responsible.
- Terminal used.

The movement week and period details are determined from the calendar and period files, and set to either the current or next week/period.

You can hold movement history on the system as long as necessary but not less than one month. This information is used to prove the closing balance at the end of the period. It is available for both Enquiry and Reporting to assist investigations into stock inaccuracies and provide the basis of activity analysis.

Stock Counting

Inventory Management provides a simple to use stock counting procedure which incorporates cycle counting. This enables the automatic creation of count recommendations. The following steps are involved:

- Count creation - this is done manually by item ranges, or automatically on a time based cycle.
- Review and maintain count recommendations.
- Request printing of Stock Count sheets.
- Enter counted Stock figures.
- Reconcile Stock Count.
- Post adjustments if applicable.

Products are selected for stocktake by any of the following options:

- Product Number.
- Product Type.
- Product Class.
- Product Group Major.
- Product Group Minor.
- Stockroom.

The application records the stock level of the selected item(s) at the start of the count. This enables everyday processing of movements to continue while stock is being counted and reconciliation to take place on completion of the count. Stocktake count sheets are then produced to the required detail, that is, all levels of inventory records are exploded for the selected items. These may be used as input documents to the following processes.

The total quantity of physical stock of each product counted is entered from the stocktake sheets. This data is validated and a report produced.

Until the stocktake is deemed complete, a reconciliation report of physical stock versus computer stock count is available. This would normally be selected by the same parameters as used when requesting the original stock count sheets. The report highlights the differences between physical and computer figures with actual quantities and value variance. This is to help assess the importance of any discrepancy. On completion of the stocktake the application offers the option to generate automatic adjustment of any unresolved discrepancies. Any variances outside the tolerances defined on the stockroom count profile are designated as count errors.

Tip: Once the count sheets have been requested, no stock movements should take place for the selected products until after the physical counts have been entered and reconciled.

To assist in the reconciliation of any discrepancies a report is available giving summary or detail information of stock movements.

Stock Management

Inventory Management offers a number of stock management techniques including Material Requirements Planning and Distribution Requirements Planning. The Inventory Management application, even in isolation, can be used to operate an order point stock management policy. The main factors in this policy are:

- Average Usage.
- Reorder point and maximum stock.
- Reordering rules.

Average Usage

The usage of an item is held on the stock history file and is maintained either weekly or monthly according to the usage cycle specified on the company profile record. Average usage is re-calculated during week or month end processing as appropriate.

The usage profile defines which of the preceding weeks or months usage are to be included in the calculation of average usage. The product stockroom balance record holds the code for the usage profile which will be used in the calculation of average usage.

Typically usage profiles will be set up to represent:

- Three months moving average.
- Twelve months moving average.
- Seasonal moving average (This would be achieved by taking the previous month and the next month last year).

Note: Care is taken to ensure that the average is only calculated from the start of the products life even though the profile indicated that previous data should be included. This is to ensure that the average is not distorted by the absence of history data.

Reorder Point And Maximum Stock

The parameters of maximum stock, reorder point, reorder quantity and economic order quantity may be maintained for each product in each stockroom. Alternatively, by using the historical usage information, maintained as a result of all movements, the application can calculate these figures. These calculations are based upon grouping products into the categories defined on the stock weeks matrix:

Nine categories are used:

1	Low value	Low usage
2	Low value	Medium usage
3	Low value	High usage
4	Medium value	Low usage

5	Medium value	Medium usage
6	Medium value	High usage
7	High value	Low usage
8	High value	Medium usage
9	High value	High usage

The definition of these groups is held on the stock weeks code matrix which is updated as part of the company profile maintenance procedure.

Limits are set to define the boundaries for high, medium and low usage and value. Minimum and maximum stock holdings, expressed as weeks at average usage, are assigned to each of the nine categories. The minimum stockholding in weeks is the number of weeks stock that will be left after the lead time has expired, and therefore, represents a safety stockholding. Safety stock is a measure of how likely the lead time and average usage are going to increase.

When the procedure to calculate Reorder Point, Maximum stock, and so on, is run, the application reads the stockroom records and re-assesses, for allowed products what the reorder point and maximum stock quantities should be.

The application assesses where the product falls on the value axis of the stock weeks matrix based on its cost. It then determines where it falls on the usage axis based on its average usage.

having assessed which of the nine categories this product falls into, the minimum and maximum stockholding (in weeks) are taken from the matrix and the following calculations performed:

Reorder Point = (Lead Time + Minimum stockholding) * Average Usage

(Lead time and minimum stockholding are expressed in weeks)

Maximum Stock = (Lead Time + Maximum stockholding) * Average Usage

(Lead time and maximum stockholding are expressed in weeks)

Reorder point and Maximum stock are held on the product stockroom balance record.

Tip: Since average usage is used in the calculation procedure, it is best run after the week end or month end processing procedure in which average usage is re-calculated.

The application is also able to calculate an Economic Order Quantity as follows:

$$EOQ = \sqrt{(2 * AU Y * OPC) / ((IC * SCR) / 100)}$$

EOQ = Economic Order Quantity

AUY = Average Usage Per Year

OPC = Order Placement Cost

IC = Item Cost

SCR = Stock Carrying Rate %

Reordering Rules

The application supports five different reordering policies:

- Up To MAX - When expected stock drops below the reorder point the system suggests that an order be placed of sufficient size to take the stock level up to the maximum.
- Reorder Quantity - When expected stock drops below the reorder point the application suggests that the reorder quantity be ordered. This quantity is either set by the user or determined by the application. A Reorder Quantity Factor can be held at stockroom level or a default is held on the Company Profile. If the reorder quantity factor was 30%, the application will recommend action to reorder enough stock to last through 30% of the lead time. If the factor was 200% the application will recommend action to reorder enough stock to last through twice the lead time.
- Up To ROP - When expected stock drops below the reorder point the application suggests that enough stock should be ordered to take the level up to the reorder point again. For example, if the reorder point was set to zero, this rule is the one that would ensure that goods were only reordered when there is demand for them in the form of a customer or manufacturing order.
- Up To Min - When expected stock drops below the reorder point the system suggests that an order be placed of sufficient size, to take the stock held up to the minimum level.
- EOQ - When expected stock drops below the reorder point the system suggests that an order be placed for the calculated or maintained economic order quantity.

Available/Expected Stock

These are calculated as follows:

Available Stock = Physical Stock - Frozen Stock - Allocated Stock - Picked stock

Expected Stock = Available Stock + Stock In Transit + Stock On Supply Order - Stock On Back Order - Stock Reserved

Periodic Processing

Although the Inventory management application is a transaction based system which records events as they happen, many of the decisions concerning stock levels and raising and amending orders are based upon the performance of a product over time. In order to make these decisions it is necessary to be able to view previous periods' activity. This is achieved by maintaining history files, not only of the transactions, but also summarised by type of transaction. These are maintained by running weekly, monthly and year end procedures.

Lot, Grade And Potency

The application enables the recording and maintenance of a range of lots, batches or serial controlled lots and their associated grade, potency, status and availability dates and times. This information is detailed on a lot header which applies to a whole lot irrespective of the lot's location.

- The grade, potency and stock status can be maintained and any modified information is held on file so that history enquiries and audits are possible.
- The location of the lot can be traced and issues, receipts and stock movements details displayed.

Enquiries

The enquiries in the Inventory Management application allow a multi-layer view of a style/product. These layers are:

- Company stock summarised by stockroom.
- Full details of the current balance, usage, and cost at a stockroom.
- The breakdown of a stockroom balance into the batches or lots that comprise the stock holding.
- The movements that gave rise to the present balance.
- The summary of activity for previous periods.

In addition, the reference files are supported by a full range of enquiries.

Reports

The reports produced by Inventory Management can be classified as:

- Status.
- Audit.
- Valuation.
- Movement Analysis.
- Action.

Status reports are provided on the master files and particularly on the item file. Audits with before and after images are printed on request. These include all changes since the previous print.

Most of the reports are supported by both selection and sequence parameters. This helps to minimise the processing time and the amount of paper required.

Implementation Considerations

This section describes the recommended procedures to help you achieve a successful implementation of your new application. This is only intended as a guide to the procedures. When you have read this section and decided on the way in which you are going to set up your application, you should refer to the relevant sections which follow for more detailed information.

It is of vital importance to the success of any software implementation that some fundamental issues of the implementation are considered before any detailed steps are undertaken. In the case of Inventory Management these issues are as follows:

- How do you wish to use Inventory Management and other applications?
- How many Inventory Management companies do you intend to set up?

These issues are usually closely linked, and this section deals with each issue in turn.

Associated Applications

The fundamental point to consider here is what functions do you intend Inventory Management to fulfil? Are you intending to use Inventory Management on a stand-alone basis, and to record all stock movements through its own procedures? If this is the case then this obviously simplifies the implementation, as you only need to be concerned with the set up requirements for Inventory Management.

If, however, you are installing other applications, then your Inventory Management implementation needs to take into account the requirements of those applications. As Inventory Management is a pre-requisite for all the Customer Service, Logistics and Production applications of the system, you can appreciate the need to consider its use in relation to the other applications.

Where Inventory Management is installed with other applications it provides:

- The basic database definition of parts/styles, stockrooms and code descriptions.
- The central repository for information on stock holding, whether at stockroom or lot level.
- The central audit of stock movements and history.
- The source of costing information for the valuation of movements and stock holding.

Other applications, therefore, use Inventory Management as shown in the following examples:

- Purchase Management uses the Inventory item definition; holds on-order information as a stockroom balance quantity; and posts movement transactions to Inventory Management for receipts and returns.
- Sales Order Processing uses the Inventory item definitions; makes use of parameters defined on the descriptions file; holds back order and allocation quantities as stockroom balance fields; and posts movement transactions to Inventory Management for customer issues and returns.

- The Production applications use the Inventory basic item definitions; hold on-order and allocation quantities as stockroom balance files; and post movement transactions to Inventory Management for production order issues and receipts.

In a full implementation, Inventory Management provides both basic data definitions and a transaction repository for a number of other applications. This is, of course, in addition to the functions which are only available within Inventory - that is, the Stock Management and Stock Taking facilities, and the Stock Adjustment Transactions.

When planning your implementation it is important that you consider:

- Which other applications do you plan to install?
- What requirements, in terms of data, will these applications look to Inventory Management to fulfil?
- How will the various stock movement requirements of the business be satisfied - by Inventory Management, or by one of the other applications?
- Will any non-standard/vertical applications require an interface to Inventory Management?

It is important that these sorts of questions are addressed at the planning stage. Inventory Management has a central role in any implementation, and subsequent changes are, therefore, difficult to make without disrupting the operation of other applications. It is worthwhile spending time early in the implementation to plan your use of Inventory Management and its relationship with other applications.

Inventory Management Companies

Inventory Management, like all other applications, allows the simultaneous operation of discrete companies. Multiple companies are used for many reasons, but the major uses are either organisational, or for testing purposes.

A decision to set up multiple Inventory companies for organisational reasons may very well be taken because you require separate inventories. It is more likely, however, that multiple Inventory companies are required because you have separate operational organisations.

For example, you may require separate selling organisations to be reflected in separate companies in the Sales Order Processing and Invoicing application. In a standard installation, this requires separate Inventory Management companies to be created. Inventory Management companies interface on a one-to-one basis with companies in Purchase Management, Requisitioning, Sales Order Processing and Invoicing, Sales Analysis, Telesales, Distribution Requirements Planning and the Production applications.

It can, therefore, be seen that any decision about the use of companies in Inventory Management needs to be taken in terms of the broader implementation.

Basic Data Set Up

Having decided on how you will use Inventory Management in conjunction with other applications and the companies you will use, you need to plan and implement the setting up of the basic data required for the application's operation. The main elements you will need to create are:

- Company profiles.
- Stockrooms.

- Stock weeks matrices.
- Usage Profiles.
- Descriptions.
- Stockroom Details.
- Alternatives.
- Calendars.

The maintenance of these elements is covered in detail in the Application Set up Data section. It is sufficient here to highlight particular issues to bear in mind when planning the implementation.

Two points which may ease the actual setting up of the data are:

1. The use of the Copy Company utility - this is the function which can be used to set up new Companies within Inventory Management. The essential description codes are set up automatically as part of this routine, if a company is created from the company shipped with the application.
2. You may choose to convert some of the volume elements, such as item and Stockroom Details, from an existing system. If you have high volumes this is particularly useful and will obviously save a significant amount of data entry time.

Company Profile

The issues you should address prior to setting up company profiles are:

- Which costing method do you intend to adopt as a company standard? (Standard, Latest, Average and FIFO are available.)
- How do you intend to make use of the user-defined specifications?
- Do you want average usage calculated on a weekly or monthly basis?
- What is to be your default reorder policy?

Stockrooms And Stock Weeks Matrices

You will need to decide how many stockrooms you require. Remember that these may be physical stockrooms or they may be logical stockrooms, for example Quarantine or Written-off stock. For each stockroom you will need to define:

- Whether the stockroom is to be included in stock valuation.
- Which transactions are allowed.
- If the stock management facilities of the application are to be used, you will need to define the stock weeks matrix for the stockroom. Therefore, you will define the parameters of value and usage for the nine item categories, along with the preferred stock levels for each category.

Usage Profiles

The application will automatically calculate average usage based on user-defined profiles. You will need to decide how many of these profiles you need to reflect the different patterns of demand in your business.

Descriptions

The Inventory Management application holds a file of parameter codes and descriptions which is used by itself and other applications. These codes cover such elements as product groups, product types, units of measure, reason codes, and so on. The major codes, that is, the subject headings, are set up automatically if you use the copy company utility to create your company data initially. Before any further data set up can take place you need to decide on the codes which you will require for each of these major headings.

Items

There are a number of issues to resolve prior to setting up your basic item definitions:

- Prior to setting up items - stockrooms must be set up.
- How are the items to be coded? It is generally recommended that the item number should merely be a unique code to identify the item - not a meaningful or structured code.
- How will you use the major analysis codes which can be associated with a item - product major group, product minor group, product type and product class? These codes are important, as many reports allow selection and sequencing by them.
- What are the valid units of measure that you will require?
- Will any parts be subject to a costing method which is not the company standard?
- Which General Ledger accounts do you wish to associate with the item for General Ledger updates.
- What level of control do you wish to exercise over individual items? Do you require lot/batch control, or is part/stockroom the lowest level you require?

Stockroom Details

You must set up a stockroom details definition for each item you wish to hold in a stockroom. The issues to be decided here are:

- What units do you wish the stock balances and unit costs to be expressed in?
- What are the rules regarding the preferred stock level of this item in this stockroom? Are they to be set automatically, or manually? Which re-order policy and usage profile are to be used?
- What is the standard cost?
- Who is your preferred supplier?

Alternative Products

Alternative products are used within the Sales Order Processing & Invoicing application, but are set up and maintained in Inventory Management.

Tip: If you do set up alternatives, it is important to decide whether a relationship is reversible.

Calendars

Immediately prior to processing you will need to set up the current year, period and week details via calendar maintenance. You must also insure that week and period end dates have been set up for the current year.

Note: It should be noted that before processing begins for a new year you need to ensure that the end dates are set up.

Initial Stock Balance Take On

Once all the basic data has been set up, you are then ready to appoint the initial stock balances prior to processing. This task may be undertaken as part of a conversion from another system, but where this is not the case the following inventory movements can be used.

- Physical Stock - use the Miscellaneous Receipt transaction to set the initial shelf stock.
- Allocated Stock - use the Allocation Adjustment transaction to set any existing allocated stock level.
- Frozen Stock - use the Frozen Stock Adjustment transaction if you currently have stock which is unavailable for issue.
- Purchase Order - use the Record Purchase Order transaction to reflect the current supply situation.

It is worthwhile entering these movements all with a narrative indicating INITIAL SET UP, so that they may be readily identified in future. Making use of a standard procedure for this exercise means that a full audit is maintained in terms of movement records.
