Chapter 7

Sales Order Processing Overview

Introduction

To facilitate the growth and expansion of a company, the package has incorporated multi-currency and European functionality. European functionality calculates the correct VAT and identifies the payment terms for the order.

The module is designed to support a rapid 'data entry' style of order entry for use when very few changes or overrides are required. Transcriptional order entry supports the greatest level of flexibility including a prompt to assist in offering an alternative item or sourcing from another depot.

Although the module contains a variety of pricing and discounting routines, in certain circumstances it is necessary to enter a negotiated price or discount. The order will be suspended if non standard conditions arise during entry, such as zero pricing or credit check failure. This allows order taking to continue unhindered, but errors are trapped.

Day to day decisions are supported by a range of enquiries which enable; stock availability to be projected into the future, customer credit to be examined and orders to be displayed by customer's reference, item number and account.

Relationship to Other Modules

The Sales Order Processing module is a fully standardised module and operates under the control of System Manager. When the Sales Order Processing module is installed, two major areas must be considered. These are:

- Whether the pre-requisite modules have already been installed and, if so, whether they set up in a way which is suitable for the operation of Sales Order Processing.
- The ways in which the functions and facilities of the Sales Order Processing module are used to satisfy the company's basic needs.

The following modules are pre-requisites to Sales Order Processing:

- System Manager
- Inventory Management
- Accounts Receivable

Normally, Sales Analysis would be installed with Sales Order Processing to provide flexible enquiry and reporting on the sales activity of the company.

Document Processing can be installed to provide the ability to produce combined despatch and delivery notes, if required.

A company must be defined within the Inventory Management module before it can be available in the Sales Order Processing module. Similarly, Sales Order Processing will raise invoices for all despatches made from the company and it will expect to post them to the customers' accounts in Accounts Receivable.

There is, therefore, a simple relationship between the modules for one company; Accounts Receivable, Sales Analysis and Sales Order Processing modules must share the same two character company code.

A number of Sales Order Processing functions depend directly on data held in the Accounts Receivable and Inventory Management modules. These are:

- The currency of the Sales Order Processing module. This is determined by the currency setting for the Accounts Receivable company.
- The currency of a customer is determined by the currency setting on the customer's Accounts Receivable account. However, this can be changed at order level.
- Sales Order Processing may only sell kits which have been set up and maintained within the Inventory Management company.
- Only alternatives set up in the Inventory Management company will be prompted as replacements for shortages during sales order entry.
- Stock allocation is usually performed by examining the order and choosing the stockroom/depot for the order line. In order to provide a larger picture of the stockroom movement, allocation by item is now possible. The items must be defined to a valid Sales Order Processing depot.
- The payment terms and discounts are defined in the Accounts Receivable customer account. These parameters are essential for an accurate

calculation of the invoice, and the invoice release date. These can be re-defined for a customer at the order level.

- Sales made for kits can update Sales Analysis in a number of ways. These options are controlled on the Item Master record.
- The analysis codes on the Item Master record are not only used within the Inventory Management module for reporting, but also form the basis of Sales Analysis. Considerable care must be taken to ensure that the coding structure set up will meet the analysis needs for the foreseeable future. This is because the regeneration of the Sales Analysis database can take a long time.

Application Configuration

Sales Order Processing can be operated for a number of companies, the characteristics of each being maintained on a control file. The module is controlled by setting up data for both the company and each depot. This would normally occur after the Inventory and Accounts Receivable companies have been created. The Accounts Receivable, Inventory, and Sales Order Processing modules all use the same company codes for interfacing.

Certain data and policies may be set up as a default at the company level. These are:

- Company name and address
- Document reference numbers for orders and invoices
- Defaults for additional customer details
- Borders printed on documents
- Nominated fields for use as search arguments for customer selection

These policies and parameters will be used throughout the operation of the system unless overridden at customer or order level. When the Inventory module is set up, a number of stockrooms may be created. These will be created for a number of purposes, only some of which may be concerned with sales and distribution.

Any stockroom from which sales are to be made must be designated as a depot and defined as a depot within Sales Order Processing. As well as address and contact information, allocation parameters can be maintained for each depot. The other essential factors that need to be considered before the order process can be fully operational are:

- Company profiles
- Depot profiles
- Price & discount lists
- Customer details
- Descriptions
- Items
- Alternatives
- Kits

Company Profile

The module requires defaults to be set up prior to undertaking the order process. These can be defined in the company profile, and will apply to all the customers within this company. The issues that need to be addressed are:

- Will you wish generally to allow back orders and part deliveries?
- What is the default priority which you wish to give to new orders, and what are the steps by which that priority is to be incremented when allocation fails?

- Do you want to allow the option of forced allocation, i.e. allowing the operator to commit more than the available stock?
- Do you, as a rule, wish to price orders at order, or despatch time?
- Which fields in the customer database do you wish to use to form part of your customer search facility?

Application Reference Data

There are a number of common features in the way in which data is maintained within the system. These are:

- The standard item search routine which is used to identify items
- The standard name and address search routine which is used to identify customers
- The standard method for selection of a code or item from a displayed list The following reference data can be maintained: Standard Codes and Descriptions
- Customers
- Prices and Discounts

Standard Codes and Descriptions

A descriptions or parameters file is used by most modules for a number of purposes. Primarily, it enables codes to be set up with standard descriptions. This provides for validation at the time of data entry and also the display of descriptions on both screens and reports. In some specific instances a parameter or number is also stored. For example, the case of value added tax percentages.

The module has a small number of standard codes and parameters that must be present for the successful operation of specific functions. These are commonly maintained in the Inventory Management module as it is the base module for both Customer Services & Logistics and Production modules.

However, they can be maintained from most modules, including Sales Order Processing. There are codes specific to Sales Order Processing which you will need to set up, for example customer classes, cash discounts, extra charges, sales analysis groups etc.

Customers

The information held in the system for customers is of equal interest to those managing and collecting the debt as to those recording and progressing sales orders. The maintenance routines in each module reflect their specific requirements. They both, however, create and maintain a common database with access to common and exclusive information. For example the Sales Order Processing module provides functions to control stock allocation, pricing and sales analysis coding.

The structure of customer information can be manipulated to match the structure of the customer's organisation. Customer accounts can be set up as single accounts, or as 'statement accounts' with many 'invoice to accounts', each of which may have many 'delivery accounts'.

Statement Account

This is shared with the Accounts Receivable module. This is created in Accounts Receivable. The data held at this level includes credit details, Accounts Receivable parameters and statistical codes.

Invoice Account

If the statement account address is not the same as the invoice address, a separate invoice account needs to be set up in Sales Order Processing. This account does not have sales orders assigned to it. Instead the despatch account contains a field in which you can identify an invoice account. The invoice account will contain the address of the customer where the invoice for those deliveries should be sent.

Despatch Account

Many despatch addresses may be set up for an account. This is done by adding a three-character suffix to the eight-character statement account code.

Additional Information

Each account to which items are delivered may have additional data to act as defaults during order entry. It includes data on sales depot, price list, discount list, allocation priority, back order parameters, part deliveries and analysis codes. This enables different parts of a customer's organisation to have different commercial terms and be serviced from a different depot.

Prices and Discounts

The system provides for pricing to be performed at both order entry, using customer and item criteria, or at despatch. Alternatively, prices and discounts may be set manually. Many price and discount lists can be set up. This may be necessary for a number of reasons, for example, different market sectors, customers or multiple currencies.

Discounting can be based upon quantity or value and may be given in terms of percentage or value. A discount may apply to an item, a range of items or the whole order. Customers may be entitled to settlement discounts depending on their method of payment and their terms. However, certain considerations must be examined before setting up the price list:

- Who, within your organisation, will be allowed to maintain lists? This authority is specified on the price/discount list profile which must be set up for each list.
- How many lists do you require? Will you wish to set up lists which are unique to individual customers, or for use on special orders?
- Within your discount lists, will you be able to specify discounts for groups of items, or are they to be specified for individual items? Will you use whole order discounts?

Effectivity dates can be used to control the module of new prices and discounts.

Price Lists

A price list can be used throughout the company or for an individual customer. Price lists are identified by a code which is held as part of the customer additional information.

The item entries within a price list have an effectivity start date so that price changes may be entered on the system in advance of their commencement.

Global increases by percentage can be applied to an individual price list. A new list may be created by copying an existing list.

Discount Lists

A discount list can be applied throughout a company or to an individual customer in a similar manner to price lists - the appropriate code being set up on the customer additional information record.

Discounts can be based on quantity or value breaks, either in the form of a percentage or an amount.

A discount can be allocated to an individual item, or alternatively the same discount can be given to all items in a discount group. A discount group is an attribute of an item and is set up in Item Maintenance to group related items for discounting purposes.

Order Processing Cycle

Sales Order Processing has five main procedures:

- Enter order details
- Stock allocation
- Pricing, discounting and credit checking
- Pick items from stock and despatch
- Raise invoice

Each one of these procedures has a number of tasks each with a large number of options.

Enter Order Details

The Sales Order Processing module provides two major types of order entry. The first is designed for rapid data entry with no dialogue with the customer at the time of entry. This would typically be used where orders have previously been entered on an order pad, and a high customer service level means that most items will be allocated and thus, few overrides are required, for example changing stockrooms.

To complement this, conversational order entry is designed to support a dialogue with the customer, offering alternatives in a short stock situation and agreeing price and discount changes.

Both types of order have three phases:

- Order header
- Order lines
- Extra charges

Order Header

The customer is identified and the standard defaults such as pricing, allocation rules, currency, supplying depot and trading terms are retrieved. The currency of an order may be changed to any currency specified in the General Ledger if the customer is able to place multi-currency orders. The payment terms for the customer can be overridden on this level, to include cash and staged discounts.

Order Lines

For transcriptional order entry, a data entry form is displayed to allow high speed entry of many order lines. Validation is performed when the entry is complete. Pricing is normally automatic, although overrides are possible. Stock allocation is performed in a batch run when all of the order lines due for despatch are matched against available stock.

Conversational orders are entered one item at a time with the opportunity to discuss availability and offer alternatives. In this instance stock allocation is normally interactive, taking into account the required due date for the order line.

Extra Charges

Standard extra charges are held on the descriptions file. These may be viewed and added to an order during the closing procedure. The actual charge value may be retrieved from the file or entered specifically for the order.

Order Acknowledgement

As a way to inform customers that their orders are being processed you have the option to print out acknowledgements.

Stock Allocation

When an order line is considered for allocation, whether interactively or in batch, the due date is compared with the allocation time fence for the depot (this time fence is the number of days required to prepare and deliver orders to the customer). Thus stock is allocated as late as practical and maximum flexibility is retained.

During batch allocation it is necessary to sequence order lines for allocation to enable high priority orders to be met. The priority of an order can be taken from the customer or entered at order time. If low priority orders are not satisfied their priority can be increased automatically. This means that at the time their priority becomes the highest and they take precedence.

During stock allocation you may find stock shortages, so it is possible to identify alternatives.

Alternative items and kit lists are used within the Sales Order Processing module, but are set up and maintained in Inventory Management. If you do set up alternatives, it is important to decide whether a relationship is reversible. Where kits are used, the issues relating to the update of Sales Analysis need to be addressed, such as whether details of the whole kit, parent only or components only should be passed. The indicator governing this update is maintained on item definition in Inventory Management.

Pricing, Discounting And Credit Checking

In order to get the full benefit from computerised Sales Order Processing, pricing and discounting should be performed by the system. This means that it must have a fundamentally flexible approach to pricing and discounting. The actual price and discounts charged are a function of the trading relationship with the customer, therefore, the trading currency is assumed to be the prime currency of the customer's account. Similarly the price list to be used and the discounts to be given are taken from the 'deliver to' account of the customer. This information is part of the additional data held for customers.

If a price is not found for the nominated list then the optional default price list will be used; this is conditioned by customer. If a discount is not found for the nominated discount list then the default discount list (ALL) is checked.

It is normal for the prices charged on the invoice to be dependent upon the date the order is received. There are a small number of instances where the price and discount is determined at the time of despatch. The Sales Order Processing system provides for these decisions to be made for the company in general, or specifically for the order. Prices and discounts are defined as follows:

Price

In the prime currency of the customer account. Taken from a price list at order entry or despatch.

Entered and fixed at order entry. Expressed in the selling units of the order (multiplied by a conversion factor on the price list if required).

Discount 1

A percentage determined as either:

- a discount for the item as given on the discount list, depending upon the quantity or value of the item sold.

Or

- a discount for the item group given on the discount list, depending upon the quantity or value of the item sold.

Discount 2

A percentage determined as a discount for the whole order as given on the discount list, depending upon the value of the whole orders.

Credit Checking

Credit checking does not prevent the entry of an order into the module. However, orders that fail a credit check are suspended, i.e. are ignored by stock allocation and have to be released. Credit checking is performed when:

- The order is entered, in which case the outstanding debt is compared with the credit limit and the credit stop flag is checked.
- Allocation takes place, when the outstanding debt and the current outstanding allocations are both considered. This is checked by calculating the:

- *Allocated value of the order + credit commitment*
- where the credit commitment is the sum of the current balance, the value of outstanding orders, the value of goods despatched not yet invoiced, plus the value of any bills accepted or at risk

The module provides for the storage of two credit limits - commercial and insured. The commercial value is used for credit checking purposes. Orders for customers who have exceeded their credit limit are suspended with the code 'CL', and for customers who have been placed on credit stop with the code 'CS.'

Hierarchy Credit Checking

The credit check and account summary balance update functions within Sales Order Processing, take account of any payment hierarchies in which the customer is defined. i.e. Consider the following hierarchical relationship:

Key: Credit limits in bold

When the credit checking process takes place it is performed at each level. (Refer to the diagram whilst following the example).

Example 1:

ABC place an order for £180: CO1A/, CO2B/, CO3A/ and CO4/ credit limits checked. If the credit check passes, stock allocation takes place and the credit commitment is increased.

ABC place another order for £50: the first order is not yet cleared, therefore the available credit is currently at £0.00. CO1A/ fails the credit check. The order is suspended and reason code 'HL' is assigned to it.

DEF place an order for £180: CO1B/ credit limit is checked and passed. But when CO2B/ credit limit is checked the order is suspended, code 'HL'.

The reason for this is that the available credit for CO2B/ has been reduced to £70 after ABC placed their order (account is still outstanding).

The credit checking process will also examine the status of the customer's account. The account may be flagged to indicate it is on hold for a number of reasons, e.g. too many outstanding debts, legal proceedings in progress. If this is the case higher up in the hierarchy it will affect the customers that are defined in the lower levels.

Example 2:

Account CO3A/ is stopped and ABC place an order for £50: CO1A/ and CO2B/ accounts pass the credit checking process. However, the order is still suspended as the higher account CO3A/ is on hold. This will be indicated by the suspension code 'HS'.

Or

Account CO4/ is being taken to court and ABC place an order for £50: account CO1A/ CO2B/ and CO3A/ all pass the credit checks. But the order is again suspended as the higher account CO4/ has been flagged as status L. At order entry the suspension code 'HT' will be assigned to the order.

Note: The suspension codes can be viewed by the description enquiry in the menu. They are held in the description file, major type 'SUSP'.

Refer to the Hierarchy Account for more details on the hierarchical customer structure.

Hierarchy Accounts

The hierarchical account structure is a feature within Sales Order Processing. The system will allow you to have up to 4 different levels of customers, whereby, you can have a parent account with a lower level of ordering customers.

For example, XYZ HQ is the parent customer and the XYZ retail shops are the second level of customers.

The levels are described below:

Level 4:

This is the highest level. It can be used to identify a parent establishment, which is likely to receive summaries of lower level activities, e.g. UK HQ. However, it is not a mandatory account and you are not permitted to assign any orders to it.

Note: You can have vertical and horizontal branches of level 4 attached to existing level 4 accounts.

Level 3:

Although no orders can be assigned to this account level, this is a mandatory account, e.g. London Office. It is used for financial account posting into the General Ledger, using the Accounts Receivable balance

Note: You cannot have vertical branches of level 3. But you can have horizontal accounts of level 3 attached to a level 4 account.

Level 2:

This is an optional account, e.g. South London Office. No orders can be assigned to it. Its purpose is purely financial for cash allocation. Refer to the cash allocation of Accounts Receivable for more information.

Note: You can have both vertical or horizontal branches of level 2 attached to level 2 or 3 accounts.

Level 1:

This is the lowest level of account possible. All orders are assigned to customers of this level, e.g. ABC. It is mandatory for the Sales Order Processing module. The Accounts Receivables Ledger will be updated with postings from these accounts, through invoicing. Refer to Invoicing for more details on invoicing.

Note: You cannot have vertical branches of level 1. But you can have horizontal accounts of level 1 attached to level 2 or 3 accounts.

To set up and maintain hierarchy accounts refer to customer maintenance of the Accounts Receivable Product Information. The main impact of hierarchy accounts for Sales Order Processing is credit checking. This takes place at order entry and allocation, and is affected by all the levels of accounts for that customer.

Picking and Despatching

Selection is provided to ensure that only the picking documents required are actually printed. This selection can be for a number of days, a range of order numbers or a particular depot. This allows documents associated with allocated orders to be printed only when action is required. This is particularly useful in dealing with large export consignments.

When a picking note is printed all allocations, irrespective of when they were made, are included. This stops documents being produced unnecessarily. If the Warehousing module is installed, it must be used to despatch orders from warehouses in a similar manner. It is then possible to print consolidated picking lists sequenced by location.

When the order has been physically despatched the module needs updating. A number of options and facilities are provided.

- A number of despatches may be confirmed together provided that the despatch method and the despatch date are common, and the order details require no changes.
- An order can be confirmed on its own. This enables additional charges to be added.
- An individual despatch may be displayed, amended where necessary and then confirmed.

For lot/batch/serial controlled items details of lots/batches must be specified to the despatch lines. This provides the system with information for stock management and item traceability. These features are useful to locate the source of an item sent out to customers.

For example, if a damaged batch of wallpaper has been delivered to a customer, instead of freezing all stocked wallpaper, it would be more effective to identify the wallpaper batch/lot source and freeze only those from that particular batch/lot. Orders can be altered so that another stockroom/depot can be used for despatch items.

Invoicing

There are a number of ways to request an invoice. These are:

- Confirm the despatch of an order
- Request a miscellaneous invoice - with stock update
- Request a miscellaneous invoice - without stock update

There are also requests for credit notes that operate in an identical fashion to the requests for miscellaneous invoices.

When an invoice or credit note is generated in the system, prices and discounts are either taken from the order, as in the case of a confirmed despatch, or created during entry using standard rules. There is a special facility to produce a credit note that is based on an invoice. This can be used to reverse a previous invoice that was perhaps raised in error.

Having generated the invoice or credit note a procedure is run to post the transactions to Accounts Receivable and the General Ledger, and to print documents. Invoices and credit notes are printed as two separate documents.

An invoice will be raised and printed in the prime currency of the customer's account. Postings will be in both prime currency and the base currency of Accounts Receivable. The data that is passed to the Sales Analysis module will be in the base currency of the company.

Invoices can be presented to customers as:

- One invoice per despatch.
- One invoice per day.
- One invoice per week.
- One invoice per period.

The level of consolidation is defined for each customer delivery account.

This means numerous despatches to a single delivery address can be consolidated on to a single invoice. Each despatch is detailed on the invoice at line level with charges as applied.

Invoices can only be produced for a single currency, therefore multiple invoices can be processed for an invoice account within the consolidation period, for multi-currencies.

Orders raised with an invoice address override are not consolidated and will produce an invoice for each despatch.

Credits and sundry invoices are not consolidated and a separate document is produced for each one raised.

The system determines when an open invoice is to be closed, posted to Accounts Receivable and printed during the invoice print procedure. This is based on:

One Invoice Per Despatch (And Sundry Invoices And Credits)

Processed during the invoice print following creation.

One Invoice Per Day

Processed during the first invoice print after the date of consolidation.

One Invoice Per Week

Processed during the first invoice print after the Inventory week-end date for the week of consolidation.

One Invoice Per Period

Processed during the first invoice print after the Inventory period-end date for the period of consolidation.

Bills Of Exchange

Bills of Exchange may be created by the Sales Order Processing module as part of the invoice run, one proposed Bill of Exchange being sent to the customer for each invoice.

This Bill of Exchange may be signed by the customer and returned, or they may issue their own Bill of Exchange, possibly to cover several invoices. This is then registered on the Cash Management module and may be allocated against invoices in the normal way. The exposure is monitored until the Bill of Exchange is cleared.

Enquiries

A significant part of the work done in a busy sales office is answering queries. These are typically regarding:

- The status of an order
- The prices being charged and discounts given
- The date on which a delivery can be expected

Invoice or credit note queries The system provides a comprehensive range of enquiries to view:

Orders By :

- Order
- Customer
- Item
- Cross Reference (customer reference)
- Despatch notes

Invoices By :

- Invoice
- Order
- Customer
- Item

Stock Availability :

- Time-phased expected stock position.

Stock Position :

- Stock holding at each depot.

As well as these day-to-day enquires, the following module reference data can be displayed:

- Customers
- Items
- Price Lists
- Discount Lists

Reports

Reports can be grouped into reference data, status, exception and action reports.

Reference Data :

- Customers
- Items
- Price lists
- Discount lists

Status :

- Outstanding orders
- Back orders
- Stock versus outstanding orders
- List of orders

Exception :

- Unconfirmed picking notes
- Suspended orders
- Orders with zero price
- Gross margin exceptions
- Selling price overrides
- Zero value invoice lines

Action :

- Pick lists

Initial Data Take-On

Once all the basic data has been set up, you are ready to use the module to process sales orders. You may wish to convert outstanding sales orders from another module - this may be done by specially-written programs.

Alternatively, you may decide to continue to process existing orders on your old module and enter new orders, from a given date, into the new module. By this method you may gradually run down orders on the old module and build the order bank on the new, but great care must be exercised over the updating of the inventory figures.

Operational Considerations

This section describes some operational considerations.

Roles/Responsibilities

- Integration of the Sales Order Processing module with other modules
- Day-to-day supervision of the running of the Sales Order Processing module.
- System maintenance
- Utilities work
- Order entry and processing

User Profiles

- Should some users be given limited access?

Interfacing to Other Modules

- Sales Ledger
- Inventory Management
- Telesales
- Advanced Order Entry
- Warehousing
- Sales Analysis

Conversion

- Existing customers - additional details need to be set up and search paths need to be established
- Existing items - search paths need to be established
- Existing back orders - leave on the old system or re-key on to the new?

Company Profile Set Up

- What fields are going to be used for customer search?
- What operational defaults need to be provided?

Processing Orders

- What type of order entry is to be used?
- What are the company standards over the use of internal and external text?
- If transcription order entry what type of allocation?
- Dual purpose picking/despatch notes or separate ones?
- Are manual pick lists going to be used?
- What type of confirmation of despatch is to be used?
- How often should the documentation options be run?

- How often should the batch jobs be run?

Reports

- Which reports should be run?
- How often?

User Notes

- Essential

Utilities

- When should validations be run?

File Maintenance Summary

When you are setting up your system it is important that you carry out file maintenance in the right order. Points to bear in mind are:

- Company profiles must be set up first
- The descriptions file must contain the necessary codes before customers and items are set up
- Discount list profiles, price list profiles and depot profiles must exist before setting up customers.

The following would work well:

- Maintain Company Profiles
- Descriptions Maintenance
- Depot Profiles Maintenance
- Price/Discount Profiles Maintenance
- Customers Maintenance
- Price Lists Maintenance
- Discount Lists Maintenance

Descriptions File Maintenance

The Descriptions file is used by the Sales Order Processing module to define valid parameter values for the module. Parameter files are used by the system for a number of reasons. They enable codes to be used at data entry time instead of typing in long repetitive data. This also enables coded data to be checked for integrity. Once they have been set up and checked, parameter files help to ensure that data input is both accurate and acceptable to the system. Some areas in SOP where codes are used are:

- Customer sales details
- Invoices
- Prices list file
- Depot file

To aid code entry and usage the codes are grouped together in 'family' units. For example all of the sales region codes are grouped together and all of the suspension codes are grouped together. A 'family' is identified by a major type code. Each 'family' member is identified by a description code e.g. for sales region the major type is SN and the description codes are defined by the user.

The system is supplied with all of the major types that you need already defined. General use description codes are also defined, but any unique to your company will have to be defined by you.
