Chapter 8

Housekeeping

Day End Routines

1/WOH

Use this option to perform daily housekeeping procedures on your database. It is important to run this option at approximately the same time every day to make sure that you maintain data integrity.

Note: You must have exclusive use of Workshop Maintenance to run this option.

This option performs the following jobs:

- Updates the database with any serial numbers entered during the day.
- Updates all contracts for the company when run as part of the day end routine. Workshop Management only updates contracts owned by the requesting Workshop branch when run as an individual option.
- Prints the Name And Address Override Audit report for all jobs where you overwrite the site address during call logging.
- Rebuilds the engineer work points values.

Reports Produced

This option produces the following reports:

- Contract Housekeeping Error Report
- Contracts Awaiting Edit & Acceptance of Credits/Re-Invoices
- Name & Address Override Audit

To run this batch job, select the Day End Routines option.

Period End Routines

2/WOH

Use this batch job to keep the calendar in line with the period end dates defined for the company, and extend the schedule of regular planned service visits, for long-term or never-ending contracts.

You should only run this batch job once at the end of each service period, after running the Day End Routine option.

The month-end procedures include:

- Advancing the current service period:
 - If the current (system) date is equal to a period end date, Workshop Management updates the current service period to the next period.
 - If the current (system) date is not equal to a period end date, Workshop Management does not update the service period.
- Extending planned service visits for contract equipment to a further period.

Note: You must have exclusive use of Workshop Management to run this option.

Note: This routine does not affect the accounting period end. Update the accounting period by changing the field in Company Profile Maintenance.

The batch job extends the schedule of planned service visits for contract equipment as follows:

- Selects equipment with a Start Next Profile Load From period less than or equal to the current service period (plus the Minimum Number Of Loaded Service Periods from the Company Profile), for processing. Workshop Management never selects equipment with a Start Next Profile Load From period of 9999.
- Retrieves the scheduled visit profile from the contract header, the model, the model group, or the company profile, and generates visits for the appropriate service periods. If Workshop Management finds no profile it generates no extension to the scheduled visits for the equipment.
- Derives the limits for the extension as follows:
 - Start period - This is the Start Next Profile Load From period, if this is not zero. Otherwise, Workshop Management uses the earlier service period of either the contract start date, or the equipment inclusion date.
 - End period - This is the service period of the contract termination date, or equipment removal date, whichever is the earlier. If the contract is a never-ending one, the end period is the start period plus the number of service periods to load (from the Company Profile).

- Calculates the actual service period, for each relative period on the profile. Actual service period = Start period + Relative period. If the actual period is less than or equal to the end period, Workshop Management creates a scheduled visit record. Once the job reaches the end period, the processing stops.
- Produces an audit report showing each piece of contract equipment processed, the number of scheduled visits created and the period range.

Reports Produced

This batch job produces the Extend Scheduled Visits Audit Report.

Note: Once this batch job has completed successfully, you must select the Load Planned Maintenance Jobs option to convert the extended visits to actual jobs.

To run this batch job, select the Period End Routines option.

Engineer Work Points

3/WOH

Use this option to recalculate and update the work points total for each engineer in the company.

The update is part of the Day End Routine, but if you need to maintain the work point values, you can run this option.

Note: You must have exclusive use of Workshop Management to run this report.

For all engineers within a company, the batch job reads through all the outstanding job lines assigned to an engineer (that is, all job lines with a status other than complete or cancelled). It calculates and accumulates the work point values of the job lines, and updates the engineer details.

The batch job calculates the work point value of a job line by multiplying the points value associated with the piece of equipment by the average hours factor associated with the job category.

Implications

When Workshop Management automatically assigns engineers to new jobs, it uses the work point values.

If there are two, or more, engineers equally qualified to do the job (based on the engineer/territory assignment rules), Workshop chooses the engineer with the lowest number of work points, to spread the workload as evenly as possible.

To run this batch job, select the Engineer Work Points option.

Message Deletion

4/WOH

Use this batch job to remove engineer or machine messages, or both, from Workshop Management, up to a selected expiry date. You should run this batch job approximately every six months.

You can also use this batch job to report on messages deleted before a user accessed and displayed them.

Implications

You can remove messages superseded by events or with an expiry date far into the future.

To run this batch job, select the Message Deletion option.

Serious Error Report

5/WOH

This batch job prints out any serious errors logged since you last printed this report. You should undertake specific corrective action for any errors reported.

You can choose the kinds of error to include in the report.

The only serious error condition, defined in Workshop Management, is when you have not set up the daily calendar far enough ahead to handle the generation of contract visits.

You can choose whether you want to print the report, or clear the serious errors file, or both.

The report is for the whole company, not just for a branch.

Implications

Once you have printed the report, you cannot print the errors included in it again using this print option, but Workshop Management does keep the errors on the file.

You must take positive action to correct the errors. This may include updating and extending main data files, and correcting transaction records affected by the data file deficiencies.

If you set the parameter to clear the Serious Error file to 1 - Yes, Workshop Management deletes all records on the file. There is no in-built archiving process.

To run this batch job, select the Serious Error Report option.
