## Chapter 8

### Background Processing

## Background Processing Utilities

This section covers the utilities available from within Background Processing. Auto back-to-back processing deals with order entry/amend and copy orders for all orders that require to be sourced by processes other than by allocating from stock. It runs in the subsystem INBACK3 and is responsible for calling the various programmes that create requisitions for buy to order and direct deliveries or works orders for make to order lines. Also, if a sales order has been amended in which the quantities across the SKUs have been varied but with no overall change to the quantity total ordered, the amendment will be reported on and a record written to the demand exception file. These background jobs can also be started and stopped as part of housekeeping.

These order lines can be sourced by:

1. Reserve against an existing purchase or works order.
2. Create a purchase order via requisitions to fulfil the sales order line.
3. Create a purchase order via requisitions to fulfil the sales order line and deliver direct to the customer.

## Start And End Auto Back To Back Monitor

### 1/STINB & 2/STINB

These options start and stop the auto back-to-back monitor. When back-to-back sales order types have been set up for a company, this routine performs the relevant updates. Planned works orders will be created for new sales order lines for make to order items provided that the item is multi dimensional. The preferred route for the production works order will be retrieved using the sourcing rules defined for multiplant production and displayed in the Planning Route field on the Production Details screen.

Requisitions will be created for buy to order and direct delivery method sales lines. Requisitions will be created for new sales order lines which will then be turned into purchase orders once the option has been taken to create purchase orders from requisitions. Where a sales order line has been increased in quantity, the requisition will be updated accordingly.

The user ID (set up in Requisitions) both authorises requisitions and initiates background jobs and subsystems. Generally, a requisition will generate a purchase order for buy to order and direct delivery sales. A requisition can also be set up so that purchase orders are not released until authorised by a higher level of authority. In such cases, the user ID must be used to release them.

## Start And End Reservation Monitor

### 3/STINB & 4/STINB

These options start and stop the Stock Reservation Monitor. This monitor performs the updates of the sales orders when a back to back (or direct delivery) purchase receipt has been made.

**Warning: The subsystem INBACK3 in library OSLINP3 must be started first.**

This option is only valid when the Advanced Order Entry and Purchase Management applications are installed. If no stock is available for an order, a purchase order can be automatically raised. Through Advanced Order Entry it is possible to reserve against this outstanding purchase order. If the reservation monitor is running, when the goods are received the job automatically identifies them as having been reserved against a sales order and allocates the goods to the appropriate sales order. Another background job that runs in the subsystem processes the purchase/works order receipts and allocates the received stock to the correct sales orders. In the case of direct delivery sales orders the background job will process the sales orders through to invoicing.

This procedure is submitted straight from the Background Processing using the option Start Reservation Monitor. It is stopped in a similar manner, directly from the option End Reservation Monitor.

If the reservation monitor is already running when you attempt to restart it, the application will display a window indicating when the monitor was started and by whom, press **Enter** to continue.

# Start and End Background Purchase Order Receipt Job

## 5 /STINB & 6/STINB

The option is used to capture despatched supply orders where the item was originally on Enterprise direct delivery in the demand company of the Enterprise. These items are then automatically received into the demand company. Processing is then continued by a background job.

*This is purely a computer transaction as the goods have already been delivered to the customer.*

Once this option has been run the allocation, pick and despatch of direct delivery orders is carried out in the normal way.
